Abstract

We propose a fast algorithm for computing the expected tranche loss in the Gaussian factor model. We test it on portfolios ranging in size from 25 (the size of DJ iTraxx Australia) to 100 (the size of DJCDX.NA.HY) with a single factor Gaussian model and show that the algorithm gives accurate results. The algorithm proposed here is an extension of the algorithm proposed in [4]. The advantage of the new algorithm is that it works well for portfolios of smaller size for which the normal approximation proposed in [4] is not sufficiently accurate. The algorithm is intended as an alternative to the much slower Fourier transform based methods [2].

1 The Gaussian Factor Model

Let us consider a portfolio of N loans. Let the notional of loan i be equal to the fraction f_i of the notional of the whole portfolio. This means that if loan i defaults and the entire notional of the loan is lost the portfolio loses fraction f_i or $100f_i\%$ of its value. In practice when a loan i defaults a fraction r_i of its notional will be recovered by the creditors. Thus the actual loss given default (LGD) of loan i is

$$LGD_i = f_i(1 - r_i) \quad (1)$$

fraction or

$$LGD_i = 100f_i(1 - r_i)\% \quad (2)$$

of the notional of the entire portfolio.

We now describe the Gaussian m-factor model of portfolio losses from default. The model requires a number of input parameters. For each loan i we are given a probability p_i of its default. Also for each i and each $k = 1, \dots, m$ we are given a number $w_{i,k}$ such that $\sum_{k=1}^m w_{i,k}^2 < 1$. The number $w_{i,k}$ is the loading factor of the loan i with respect to factor k . Let $\phi_1, \dots, \phi_m$ and $\phi^i, i = 1, \dots, N$ be independent standard normal random variables. Let $\Phi(x)$ be the cdf of the standard normal distribution. In our model loan i defaults if

$$\sum_{k=1}^m w_{i,k} \phi_k + \sqrt{1 - \sum_{k=1}^m w_{i,k}^2} \phi^i < \Phi^{-1}(p_i) \quad (3)$$

This indeed happens with probability p_i . The factors $\phi_1, \dots, \phi_m$ are usually interpreted as the state of the global economy, the state of the regional economy, the state of a particular industry and so on. Thus they are the factors that affect the default behavior of all or at least a large group of loans in the portfolio. The factors $\phi^1, \dots, \phi^N$ are interpreted as the idiosyncratic risks of the loans in the portfolio.

Let I_i be defined by

$$I_i = I_{\{\text{loan } i \text{ defaulted}\}} \quad (4)$$

We define the random loss caused by the default of loan i as

$$L_i = f_i(1 - r_i)I_i, \quad (5)$$

where r_i is the recovery rate of loan i . The total loss of the portfolio is

$$L = \sum_i L_i \quad (6)$$

An important property of the Gaussian factor model is that the L_i 's are not independent of each other. Their mutual dependence is induced by the dependence of each L_i on the common factors $\phi_1, \dots, \phi_m$. Historical data supports the conclusion that losses due to defaults on different loans are correlated with each other. Historical data can also be used to calibrate the loadings $w_{i,k}$.

2 Conditional Portfolio Loss L

When the values of the factors $\phi_1, \dots, \phi_m$ are fixed, the probability of the default of loan i becomes

$$p^i = \Phi^{-1} \left(\frac{p_i - \sum_k w_{i,k} \phi_k}{\sqrt{1 - \sum_k w_{i,k}^2}} \right) \quad (7)$$

The random losses L_i become conditionally independent Bernoulli variables with the mean given by

$$E_{cond}(L_i) = f_i(1 - r_i)p^i \quad (8)$$

and the variance given by

$$VAR_{cond}(L_i) = f_i^2(1 - r_i)^2 p^i(1 - p^i) \quad (9)$$

By the Central Limit Theorem the conditional distribution of the portfolio loss L , given the values of the factors $\phi_1, \dots, \phi_m$, can be approximated by the normal distribution with the mean

$$E_{cond}(L) = \sum_i E_{cond}(L_i) \quad (10)$$

and the variance

$$VAR_{cond}(L) = \sum_i VAR_{cond}(L_i) \quad (11)$$

In [4] it was shown that for portfolios of 125 names this approximation leads to accurate results.

If the size of the portfolio is smaller than 125, for example 30 (the size of DJ iTraxx ex Japan) or 50 (the size of DJ iTraxx CJ), then the Central

Limit Theorem no longer provides a sufficiently accurate approximation to the conditional distribution of the portfolio loss L . An accurate representation of the conditional distribution of the portfolio loss L is given by its Hermite series expansion. For historical reasons this expansion is also known as the Charlier series expansion [3], [1].

3 The Hermite Expansion of the Conditional Distribution of the Portfolio Loss L

Let $F(x)$ be the c.d.f. of the conditional distribution of the portfolio loss L . So that

$$P(L \leq x) = F(x) \quad (12)$$

For each fixed value of the factors $\phi_1, \dots, \phi_m$ we define the normalized conditional loss $\tilde{L}$ by

$$\tilde{L} = \frac{L - E_{cond}(L)}{\sqrt{VAR_{cond}(L)}} \quad (13)$$

Let $\tilde{F}(x)$ be the c.d.f. of the distribution of the normalized conditional portfolio loss $\tilde{L}$. So that

$$P(\tilde{L} \leq x) = \tilde{F}(x) \quad (14)$$

We define the Hermite polynomial $H_n(x)$ of degree n by

$$H_n(x) = (-1)^n e^{\frac{x^2}{2}} \frac{d^n}{dx^n} e^{-\frac{x^2}{2}} \quad (15)$$

Let c_n be defined by

$$c_n = \frac{(-1)^n}{n!} \int_{-\infty}^{\infty} H_n(x) d\tilde{F}(x) \quad (16)$$

Then we have

$$\tilde{F}(x) = \sum_{i=0}^{\infty} \int_{-\infty}^x c_i H_i(t) \frac{e^{-\frac{t^2}{2}}}{\sqrt{2\pi}} dt \quad (17)$$

The series above converges in the sense of distributions (generalized functions) [5]. A good reference on the theory of distributions (generalized functions) is [5]. Let us pick a finite N . Then we have

$$\tilde{F}(x) \approx \sum_{i=0}^N c_i \int_{-\infty}^x H_i(t) \frac{e^{-\frac{t^2}{2}}}{\sqrt{2\pi}} dt \quad (18)$$

As before the approximation is in the sense of generalized functions. Equation (18) implies that the distribution of the normalized conditional portfolio loss $\tilde{L}$ can be approximated by a distribution with the density

$$\tilde{\rho}(x) = \sum_{i=0}^N c_i H_i(x) \frac{e^{-\frac{x^2}{2}}}{\sqrt{2\pi}} \quad (19)$$

The function $\tilde{\rho}(x)$ is not necessarily nonnegative and therefore may not be a probability density in the strict sense. However, as is explained in [5], this does not affect the validity of our final result (24). Therefore we may treat $\tilde{\rho}(x)$ as a real probability density.

The distribution of the unnormalized loss L can be approximated by a distribution with density

$$\rho(x) = \sum_{i=0}^N \frac{c_i}{\sqrt{VAR_{cond}(L)}} H_i \left(\frac{x - E_{cond}(L)}{\sqrt{VAR_{cond}(L)}} \right) \frac{e^{-\left(\frac{x - E_{cond}(L)}{\sqrt{VAR_{cond}(L)}}\right)^2}}{\sqrt{2\pi}} \quad (20)$$

The joint distribution of the factors $\phi_1, \dots, \phi_m$ and the portfolio loss L can be approximated by a distribution with density

$$\rho_{joint}(\phi_1, \dots, \phi_m, L) = \rho(L) \prod_{k=1}^m \rho_{G,0,1}(\phi_k), \quad (21)$$

where $\rho_{G,0,1}(x)$ stands for the Gaussian density with mean 0 and variance 1.

Observe that the coefficient c_n depends only on the moments of the distribution $\tilde{F}(x)$. Since L_i 's are independent Bernoulli random variables these moments are known analytically. Thus in the case under consideration all the c_n 's are known analytically.

If in equation (20) we set $N = 1$ we obtain the standard approximation by the normal density proposed in [4]. Thus the algorithm proposed here is a generalization of the algorithm in [4]. We show later that it gives good numerical results even when the portfolio size is too small for the normal approximation to be accurate.

4 Expected Loss of a Tranche of Loan Portfolio

Let $0 \leq a < b \leq 1$. We define a tranche loss profile $Tl_{a,b}(x)$ by

$$Tl_{a,b}(x) = \frac{\min(b - a, \max(x - a, 0))}{b - a} \quad (22)$$

Number a is called the attachment point of a tranche, while b is called the detachment point of a tranche. The expected loss of a tranche is then

$$TLoss(a, b) = \int Tl_{a,b}(L) \rho_{joint}(\phi_1, \dots, \phi_m, L) d\phi_1 \dots \phi_m L \quad (23)$$

This can be rewritten as a double integral

$$TLoss(a, b) = \int \int Tl_{a,b}(L) \rho(L) dL \prod_{k=1}^m \rho_{G,0,1}(\phi_k) d\phi_1 \dots \phi_m \quad (24)$$

The inside integral with respect to L can be done analytically for fixed values of the factors $\phi_1, \dots, \phi_m$. The outside integral has to be computed numerically. However, since it is an integral of a bounded smooth function with respect to m-dimensional Gaussian density, it is one of the simpler integrals to compute numerically.

5 Numerical Example

In this section we apply the proposed algorithm to the single factor Gaussian model of a portfolio with n names. We take n to be 25 (size of DJ iTraxx Australia), 30 (size of DJ iTraxx ex Japan), 50 (size of DJ iTraxx CJ) and 100 (size of DJCDX.NA.HY). We choose a single factor model because it is the one most frequently used in practice. For each n we compute the loss of the equity tranche with the attachment point $a = 0$ or $a = 0\%$ and the detachment point 3%. The parameters of the portfolio are

$$\begin{aligned} f_i &= \frac{1}{n} \\ p_i &= 0.015 + \frac{0.05(i-1)}{n-1} \end{aligned}$$

$$\begin{aligned} r_i &= 0.5 - \frac{0.1(i-1)}{n-1} \\ w_{i1} &= 0.5 - \frac{0.1(i-1)}{n-1}, \end{aligned} \tag{25}$$

where $i = 1, \dots, n$. Finally, we choose $N = 5$ in (18).

In Figure 1 we compare the expected loss computed using 10^6 Monte Carlo samples with the expected loss computed using formula (24).¹ The agreement between the two is good.

Figure 1: Equity Tranche Loss in the Gaussian Single Factor Model

6 Conclusions.

To obtain the results in Figure 1 we only needed to perform a single one dimensional numerical integration for each tranche. This is an improvement

¹The author has the code implementing the algorithm described here in MATLAB, VBA for Excel and C.

over the Fourier transform based methods [2] which requires computing a large number of Fourier transforms for each tranche. Each individual Fourier transform is as computationally expensive as (24).

The expansion (18) is accurate even when the portfolio size is too small for the normal approximation of [4] to be precise. Thus we developed an algorithm which is as fast as the algorithm proposed in [4] but allows us to obtain higher precision for a portfolio of a given size by including more terms in (18).
